PROBLEM STATEMENT 06 · TAVILY

THEME

AI-Powered Fact Verification & Information Freshness

Build a Stale-Answer Detector for AI Applications

Large language models can confidently generate answers containing information that is no longer accurate. Product pricing changes, APIs are updated, regulations evolve, and company leadership changes, but AI-generated responses may continue presenting outdated information as fact.

The challenge is to build a verification layer that examines AI-generated answers, identifies claims that may have become outdated, and checks them against current information from reliable sources.

GOAL

Build a system that accepts an LLM-generated answer, detects potentially stale factual claims, re-verifies them using live sources, and provides a freshness score for each relevant claim.

CORE REQUIREMENTS

1. **Claim Identification:** Analyze an AI-generated response and identify factual statements that may be time-sensitive.
2. **Freshness Detection:** Flag claims that could have become outdated, including information about pricing, API versions, laws, or leadership.
3. **Live Verification:** Re-check flagged claims against current web sources.
4. **Freshness Scoring:** Provide a freshness score for each relevant claim based on the available evidence.

EXPECTED OUTCOME

A working AI verification system that helps users identify potentially outdated information in LLM-generated responses and understand which claims are supported by current sources.

OPTIONAL IMPLEMENTATION GUIDANCE

Participants may explore verification for API documentation, software pricing, regulatory information, company announcements, or other frequently changing information. Tavily can support live web research and source retrieval, while Bifrost can manage the model requests used to analyze and evaluate claims.

MANDATORY TECHNOLOGY INTEGRATION

All submissions must meaningfully integrate both Tavily and Bifrost by Maxim AI. The project must demonstrate how each technology contributes to the solution.
